ABSTRACT

ACUTE DERMAL IRRITATION TEST FOR F10 SUPERCONCENTRATE (Batch no:100124)

The aim of the study was to determine the acute dermal irritation of F10 Super concentrate (Batch no: 100124). This study was conducted according to EPA Guideline 870.100 and 870.2500 Acute Dermal Irritation (OPPTS Harmonized Guidelines, www.epa.gov, June 21st 2007.

Young healthy albino rabbits animals with no skin lesions were admitted to the study. A veterinarian confirmed the health status of all animals.

Test substance was applied to a small area (approximately 6 cm²) of skin and covered with a gauze patch, which was held in place with non-irritating tape. Access by the animal to the patch and resultant ingestion/inhalation of the test substance was prevented by proper coverage of the test patch with non-irritating tape.

For this study the observation period after application of the test substance was 7 days.

The degree of irritation was read and scored at specified intervals and was further described to provide a complete evaluation of the effects. The duration of the study was sufficient to permit a full evaluation of the reversibility or irreversibility of the effects observed.

All 3 animals showed no signs of erythema or oedema after patch removal and at any time of observation thereafter. The control regions on the animals (where no test substance was added) showed no symptoms of either erythema or oedema.

It is therefore concluded that the F10 super-concentrate causes no dermal irritation.
